

# An Identification and Dimensionality Robust Test for Linear IV

Manu Navjeevan

UNIVERSITY OF CALIFORNIA,  
LOS ANGELES

February, 2024

Consider the linear IV model

$$y_i = x_i' \beta + z_{1i}' \Gamma + \epsilon_i, \quad \mathbb{E}[\epsilon_i | z_i] = 0$$

Researcher observes  $(y_i, x_i, z_i)'$

- Outcome  $y_i \in \mathbb{R}$ ;
  - e.g income
- Endogenous Regressor(s)  $x_i \in \mathbb{R}^{d_x}$ ;
  - e.g years of education
- Instruments  $z_i = (z_{1i}, z_{2i})' \in \mathbb{R}^{d_c} \times \mathbb{R}^{d_z - d_c}$ .
  - e.g demographic characteristics, quarter of birth

I propose a new test for

$$H_0 : \beta = \beta_0 \text{ vs. } H_1 : \beta \neq \beta_0$$

when

- Identification is arbitrarily weak;
- Errors are heteroskedastic;
- The number of instruments is potentially large,  $d_z \gg n$ .
  - Dimensionality of controls is fixed,  $d_c \ll n$ .

- **Low Dimensional:** Anderson and Rubin (1949), Staiger and Stock (1997), Wang and Zivot (1998), Kleibergen (2002, 2005), Moreira (2003, 2009), Andrews (2016).
  - Analyses treat  $d_z$  as fixed or growing slowly with sample size. Tests control size under heteroskedasticity when  $d_z^3/n \rightarrow 0$  (Andrews and Stock, 2007).

- **Low Dimensional:** [Anderson and Rubin \(1949\)](#), [Staiger and Stock \(1997\)](#), [Wang and Zivot \(1998\)](#), [Kleibergen \(2002, 2005\)](#), [Moreira \(2003, 2009\)](#), [Andrews \(2016\)](#).
  - Analyses treat  $d_z$  as fixed or growing slowly with sample size. Tests control size under heteroskedasticity when  $d_z^3/n \rightarrow 0$  ([Andrews and Stock, 2007](#)).
- **Many Instruments:** [Crudu et al. \(2021\)](#), [Mikusheva and Sun \(2021\)](#), [Matsushita and Otsu \(2022\)](#), [Lim et al. \(2022\)](#).
  - Allow  $d_z/n \rightarrow \varrho \in [0, 1)$  but use [Chao et al. \(2012\)](#) CLT that requires  $d_z \rightarrow \infty$ .
  - If  $d_z \rightarrow \infty$  slowly, asymptotic approximation may be poor in finite samples.

- **Low Dimensional:** Anderson and Rubin (1949), Staiger and Stock (1997), Wang and Zivot (1998), Kleibergen (2002, 2005), Moreira (2003, 2009), Andrews (2016).
  - Analyses treat  $d_z$  as fixed or growing slowly with sample size. Tests control size under heteroskedasticity when  $d_z^3/n \rightarrow 0$  (Andrews and Stock, 2007).
- **Many Instruments:** Crudu et al. (2021), Mikusheva and Sun (2021), Matsushita and Otsu (2022), Lim et al. (2022).
  - Allow  $d_z/n \rightarrow \varrho \in [0, 1)$  but use Chao et al. (2012) CLT that requires  $d_z \rightarrow \infty$ .
  - If  $d_z \rightarrow \infty$  slowly, asymptotic approximation may be poor in finite samples.
- **High Dimensional:** Belloni et al. (2012), Gautier and Rose (2021), Mikusheva (2023).
  - $d_z \gg n$  allowed under strong identification but limited work when identification is weak.

Even when  $d_z < n$ , it can be unclear which test, if any, is applicable

1. Bastos et al. (2018). *Export Destinations and Input Prices*, AER.

Interested in effect of Portuguese firm export destinations on prices paid for inputs.

- Instrument for firm export destinations using interactions of exchange rate movements and initial export destinations.

First-stage F-statistic on 100 instruments ( $\approx 2.5$ ) indicates weak identification.

- Authors validate results using Anderson-Rubin test, arguments about direction of weak IV bias.

**Which identification robust test to use?**

- $d_z^3 = 1,000,000 \gg n = 45,659$ ;
- $d_z = 100 \xrightarrow{?} \infty$ .

Even when  $d_z < n$ , it can be unclear which test, if any, is applicable

## 2. Gilchrist and Sands (2016). *Something to Talk About: Social Spillovers in Movie Consumption*, JPE.

Consider effect of strong opening weekend on ticket sales in later weeks. Instrument for opening weekend sales using national weather conditions.

- Unusually poor weather conditions may lead people to choose to watch a movie instead of “chilling” outside.

Start with 52 weather instruments, then use LASSO select up to three. F-statistic on selected instruments ranges from 15-38, F-statistic on all instruments is  $\approx 3.5$ .

- Unclear whether F-statistic on selected instruments is interpretable.

**Which identification robust test to use?**

- $d_z^3 \approx 140,000 \gg n = 1671$ ;
- $d_z = 52 \xrightarrow{?} \infty$

Even when  $d_z < n$ , it can be unclear which test, if any, is applicable

3. [Derenoncourt \(2022\)](#). *Can You Move to Opportunity? Evidence from the Great Migration*, AER.

Considers effect of Black Americans migration rates from 1940 - 1970 on income mobility gap in current day. Instrument for Black migration shares using “supply-side” variation.

- Focus on industry conditions for industries with historically higher than average Black employment rates.

Initial instrument set consists of 9 instruments, then use post-LASSO to estimate first-stage. F-statistic on selected variables is 14.78, on all variables is 11.68.

- [Stock and Yogo \(2005\)](#) cutoff for  $d_z = 9$  and no more than a 15% size distortion is 14.01.

**Which identification robust test to use?**

- $d_z^3 = 729 > n = 239$ ;
- $d_z = 9 \xrightarrow{?} \infty$ .

1. Test can be applied in any of settings mentioned above.
  - Relies on a nuisance parameter that is easy to estimate using “out-of-the-box” methods.
  - Incorporate first stage information using ridge regression.
2. Limiting  $\chi^2(d_x)$  distribution of test statistic is derived via direct gaussian approximation.
  - Number of instruments can be larger than  $n$ , existing CLTs cannot be applied;
  - Limiting distribution of test statistic is pivotal and does not require  $d_z \rightarrow \infty$ .
3. To improve power against certain alternatives, I propose a combination with sup-score test of [Belloni et al. \(2012\)](#).

$n$	$d_z$	$\rho$	New Test	And. Rubin	J. AR	J. LM
200	30	0.3	0.0498	0.0096	0.1090	0.0318

**Table 1:** Simulated size of various tests with nominal level  $\alpha = 0.05$  under weak identification and heteroskedastic errors. Parameter  $\rho$  controls degree of endogeneity

Details

In addition to previously mentioned results, contribute to the following literatures:

- **Weak Identification:** Nelson and Startz (1990), Bound et al. (1995), Stock and Wright (2000), Ahmad et al. (2001), Andrews et al. (2006), Hansen et al. (2008), Chaudari and Zivot (2009), Andrews and Cheng (2012), Fan and Park (2014), Cheng (2008, 2015), Chaudari et al. (2014), Andrews and Guggenberger (2019), Andrews and Mikusheva (2016, 2022, 2023).
- **Many/High-Dimensional Instruments:** Bekker (1994), Hahn (2002), Chao and Swanson (2005), Han and Phillips (2006), Anatolyev (2012), Adusumilli (2017), Gold et al. (2020), Fan et al. (2023).
- **Gaussian Approximation:** Lindeberg (1922), Chatterjee (2006), Pouzo (2015), Chernozhukov et al. (2013, 2017), Graham (2017).

# Table of Contents

---

Test Statistic

Power Properties

Empirical Application

General Case

Focus on the case where  $d_x = 1$ . With first stage, can write model as

$$\begin{aligned} y_i &= x_i \beta + \epsilon_i \\ x_i &= \underbrace{\mathbb{E}[x_i | z_i]}_{\Pi_i} + v_i \quad \mathbb{E}[(\epsilon_i, v_i)' | z_i] = 0 \end{aligned}$$

- Controls  $z_{1i}$  assumed to be partialled out of  $(y_i, x_i)$ ;
- Random variables  $\{(z_i, \epsilon_i, v_i)'\}_{i=1}^n$  independent and identically distributed;

Additionally, define the null errors  $\epsilon_i(\beta_0) := y_i - x_i \beta_0$ .

Focus on the case where  $d_x = 1$ . With first stage, can write model as

$$\begin{aligned} y_i &= x_i \beta + \epsilon_i \\ x_i &= \underbrace{\mathbb{E}[x_i | z_i]}_{\Pi_i} + v_i \quad \mathbb{E}[(\epsilon_i, v_i)' | z_i] = 0 \end{aligned}$$

- Controls  $z_i$  assumed to be partialled out of  $(y_i, x_i)$ ;
- Random variables  $\{(z_i, \epsilon_i, v_i)'\}_{i=1}^n$  independent and identically distributed;

Additionally, define the null errors  $\epsilon_i(\beta_0) := y_i - x_i \beta_0$ .

### Remark.

All results hold conditionally on a realization of the instruments. Having described basic model, treat them as fixed moving forward.

Proposed test statistic is similar in spirit to, but structurally distinct from, a jackknife version of the K-statistic (Kleibergen, 2002, Kleibergen, 2005).

- Kleibergen K-statistic influential in “low-dimensional” literature.
- Adapting Kleibergen idea for setting with large instruments requires significant modification of test statistic.

Ideal test would use first stage to test null hypothesis.

$$\text{Ideal}(\beta_0) := \frac{\left( \sum_{i=1}^n \epsilon_i(\beta_0) \Pi_i \right)^2}{\sum_{i=1}^n \epsilon_i^2(\beta_0) \Pi_i^2} \rightsquigarrow \chi^2(1)$$

- Use of first stage leads to an efficient test ([Chamberlain, 1987](#));
- Limiting distribution is straightforward to derive.

Since true first stage is unknown, could try to instead estimate  $\widehat{\Pi}_i$  using  $x_1, \dots, x_n$ ;

$$\text{Ideal}(\beta_0) := \frac{\left( \sum_{i=1}^n \epsilon_i(\beta_0) \widehat{\Pi}_i \right)^2}{\sum_{i=1}^n \epsilon_i^2(\beta_0) \widehat{\Pi}_i^2}$$

- Under weak identification, distribution of  $\widehat{\Pi}_i$  is relevant to limiting distribution of test statistic;
- Cannot approximate limiting behavior without knowledge of underlying DGP.

Partial out  $\epsilon_i(\beta_0)$  from  $x_i$ ;

$$r_i = x_i - \frac{\text{Cov}(\epsilon_i(\beta_0), x_i)}{\text{Var}(\epsilon_i(\beta_0))} \epsilon_i(\beta_0)$$

Then estimate  $\hat{\Pi}_i$  using OLS of  $r_i$  on  $z_i$ . Under homoskedasticity, resulting first-stage estimates are uncorrelated with  $\epsilon_i(\beta_0)$ .

K-statistic is constructed using these first stage estimates

$$K(\beta_0) := \frac{\left( \sum_{i=1}^n \epsilon_i(\beta_0) \widehat{\Pi}_i \right)^2}{\widehat{\text{Var}}(\epsilon(\beta_0)) \sum_{i=1}^n \widehat{\Pi}_i^2}$$

To analyze limiting behavior, apply CLT to numerators and denominators and treat variables as if they are normally distributed.

- $\{\widehat{\Pi}_i\}_{i \in [n]} \perp \{\epsilon_i(\beta_0)\}_{i \in [n]}$  since uncorrelated jointly gaussian variables are independent.
- Conditional on  $\{\widehat{\Pi}_i\}_{i \in [n]}$ ,  $K(\beta_0) \sim \chi^2(1)$  under  $H_0$ ; unconditional distribution also  $\chi^2(1)$ .

When  $d_z$  is large and errors are heteroskedastic run into the following issues

1. Cannot apply CLTs to examine limiting behavior of test statistic,
2. OLS may be poorly behaved or not well defined if  $d_z$  is large,
3. Kleibergen (2005) extension for heteroskedastic errors requires estimating a  $d_z \times d_z$  matrix
  - Cannot be consistently estimated when  $d_z$  large.

## Modified Endogenous Variable

---

I use versions of  $x_i$  that are conditionally uncorrelated with  $\epsilon_i(\beta_0)$ ;

$$r_i := x_i - \rho(z_i)\epsilon_i(\beta_0), \quad \rho(z_i) := \frac{\text{Cov}(\epsilon_i(\beta_0), x_i|z_i)}{\text{Var}(\epsilon_i(\beta_0)|z_i)}.$$

Notice that  $\text{Cov}(\epsilon_i(\beta_0), r_i|z_i) = 0$ . Will use  $r_1, \dots, r_n$  to construct first stage estimates and test statistic.

## Estimating Nuisance Parameter

---

Parameter  $\rho(z_i)$  is conditional slope parameter from OLS of  $x_i$  on  $\epsilon_i(\beta_0)$ . Under  $H_0$  it solves the population problem;

$$\rho(z_i) = \arg \min_{\tilde{\rho}(z_i)} \mathbb{E} \left[ (x_i - \epsilon_i(\beta_0) \tilde{\rho}(z_i))^2 \right]$$

If  $\rho(z_i) = b(z_i)' \gamma + \xi_i$  for a basis  $b(z_i) \in \mathbb{R}^{d_b}$  then

$$\gamma = \arg \min_{\tilde{\gamma}} \mathbb{E} \left[ (x_i - \epsilon_i(\beta_0) b(z_i)' \tilde{\gamma})^2 \right]$$

Can estimate  $\gamma$  via

$$\widehat{\gamma} = \arg \min_{\gamma} \frac{1}{n} \sum_{i=1}^n (x_i - \epsilon_i(\beta_0)b(z_i)' \gamma)^2 + \lambda \|\gamma\|_1 \quad (1)$$

- Eqn. (1) is a simple LASSO regression of  $x_i$  on  $\epsilon_i(\beta_0)b(z_i)$ .
- $\widehat{\gamma}$  converges to  $\gamma$  under [approximate sparsity](#)  $\mathfrak{A}$ , even if  $d_b \gg n$ .
  - If errors are homoskedastic,  $\rho(z_i)$  is sparse in any basis with a constant term.

For each  $i = 1, \dots, n$  define  $\hat{r}_i := x_i - \epsilon_i(\beta_0)b(z_i)'\widehat{\gamma}$ .

Using  $\hat{r}_1, \dots, \hat{r}_n$  construct a jackknife-linear estimate of the first stage.

$$\hat{\Pi}_i := \sum_{j \neq i} h_{ij} \hat{r}_j$$

The weights  $h_{ij}$  derive from matrix  $H \in \mathbb{R}^{n \times n}$  which depends only on the instruments  $\mathbf{z} = (z'_1, \dots, z'_n)' \in \mathbb{R}^{n \times d_z}$ . In paper, take  $H$  to be the ridge regression hat matrix.

$$H = \mathbf{z}(\mathbf{z}'\mathbf{z} + \lambda^\star I_{d_z})^{-1}\mathbf{z}$$

However, any other form of  $H$  is permissible so long as a balanced design condition is met.

Ridge Penalty

Alternate  $H$

Using  $\widehat{\Pi}_1, \dots, \widehat{\Pi}_n$  construct the test-statistic

$$JK(\beta_0) := \frac{(\sum_{i=1}^n \epsilon_i(\beta_0) \widehat{\Pi}_i)^2}{\sum_{i=1}^n \epsilon_i^2(\beta_0) \widehat{\Pi}_i^2}$$

The test statistic is similar in spirit to a jackknife version of the K-statistic, but the construction is distinct.

## Balanced Design Condition

---

Balanced design condition requires that the average second moment of the first stage estimators is on the same order as the maximum second moment

Balanced Design:  $\frac{\max_i \mathbb{E}[(\sum_{j \neq i} h_{ij} r_j)^2]}{\frac{1}{n} \sum_{i=1}^n \mathbb{E}[(\sum_{j \neq i} h_{ij} r_j)^2]}$  is bounded from above

- Eliminates  $H$  matrices that are all zeroes or nearly all zeroes.
- Ensures that distribution of test statistic is not governed by a single observation.

Verifying Balanced Design

### Theorem 1

Suppose that moment, balanced design, and estimation assumptions  $\mathcal{E}$  hold. Then, under  $H_0$ ,  $JK(\beta_0) \rightsquigarrow \chi^2(1)$ .

### Proof Strategy.

Limiting distribution is derived in two main steps.

1. Show CDF of an infeasible statistic, constructed with the true  $\rho(z_i)$ , can be approximated by CDF of a gaussian analog statistic.
  - Approximation holds in local neighborhoods of null, allows for analysis of local power.
2. Show that the difference between feasible and infeasible statistics converges to zero.
  - Simple statement, but not immediate as some standard tools are lost in first step of argument.

For each  $i \in [n]$ , let  $(\tilde{\epsilon}_i(\beta_0), \tilde{r}_i)'$  be generated

- (a) independently of all other variables in the model and;
- (b) with the same mean and covariance matrix as  $(\epsilon_i(\beta_0), r_i)'$ .

Define  $\widehat{\Pi}_i^I = \sum_{j \neq i} h_{ij} r_j$ ,  $\tilde{\Pi}_i = \sum_{j \neq i} h_{ij} \tilde{r}_j$ , and

$$JK_I(\beta_0) := \frac{(\sum_{i=1}^n \epsilon_i(\beta_0) \widehat{\Pi}_i^I)^2}{\sum_{i=1}^n \epsilon_i^2(\beta_0) (\widehat{\Pi}_i^I)^2} \quad JK_G(\beta_0) := \frac{(\sum_{i=1}^n \tilde{\epsilon}_i(\beta_0) \tilde{\Pi}_i)^2}{\sum_{i=1}^n \mathbb{E}[\epsilon_i^2(\beta_0)] \tilde{\Pi}_i^2}$$

Uncorrelated normal random variables are independent; under  $H_0$  distribution of  $JK_G(\beta_0)$  conditional on  $(\tilde{r}_1, \dots, \tilde{r}_n)$  is  $\chi^2(1)$  and so unconditional distribution is also  $\chi^2(1)$ .

Let  $N_I$  and  $D_I$  denote scaled versions of the numerator and denominator  $JK_I(\beta_0)$ . Likewise,  $N_G$  and  $D_G$  represent scaled versions of the numerator and denominator of  $JK_G(\beta_0)$  so that

$$JK_I(\beta_0) = \frac{N_I}{D_I} \text{ and } JK_G(\beta_0) = \frac{N_G}{D_G}$$

Interpolation argument is difficult on test statistics. Instead for any  $a \geq 0$  work with

$$JK_I^a = N_I - aD_I \text{ and } JK_G^a = N_G - aD_G$$

Notice that  $\{JK_I(\beta_0) \leq a\} = \{JK_I^a \leq 0\}$  and  $\{JK_G(\beta_0) \leq a\} = \{JK_G^a \leq 0\}$ .

One-by-one replace each pair  $(\epsilon_i(\beta_0), r_i)$  in the expression of  $JK_I^a$  with  $(\tilde{\epsilon}_i(\beta_0), \tilde{r}_i)$

$$\begin{aligned} JK_I^a &= JK^a((\epsilon_1(\beta_0), r_1), (\epsilon_2(\beta_0), r_2), \dots, (\epsilon_{n-1}(\beta_0), r_{n-1}), (\epsilon_n(\beta_0), r_n)) \\ &\quad \downarrow \\ &JK^a((\tilde{\epsilon}_1(\beta_0), \tilde{r}_1), (\epsilon_2(\beta_0), r_2), \dots, (\epsilon_{n-1}(\beta_0), r_{n-1}), (\epsilon_n(\beta_0), r_n)) \\ &\quad \vdots \\ &JK^a((\tilde{\epsilon}_1(\beta_0), \tilde{r}_1), (\tilde{\epsilon}_2(\beta_0), \tilde{r}_2), \dots, (\tilde{\epsilon}_{n-1}(\beta_0), \tilde{r}_{n-1}), (\epsilon_n(\beta_0), r_n)) \\ &\quad \downarrow \\ &JK^a((\tilde{\epsilon}_1(\beta_0), \tilde{r}_1), (\tilde{\epsilon}_2(\beta_0), \tilde{r}_2), \dots, (\tilde{\epsilon}_{n-1}(\beta_0), \tilde{r}_{n-1}), (\tilde{\epsilon}_n(\beta_0), \tilde{r}_n)) = JK_G^a \end{aligned}$$

And show that sum of one step distributional changes is negligible as  $n \rightarrow \infty$ .

# Gaussian Approximation

---

Apply Glivenko-Cantelli type argument to show approximation holds uniformly over  $a \in \mathbb{R}$ .

## Lemma 1

Assume [moment and balanced design assumptions](#) [hold](#). Then, in local neighborhoods of  $H_0$ ;

$$\sup_{a \in \mathbb{R}} \left| \Pr(JK_I(\beta_0) \leq a) - \Pr(JK_G(\beta_0) \leq a) \right| \rightarrow 0 \quad (2)$$

Local Neighborhoods and Infeasible Consistency

Final step is to show that the difference between feasible  $JK(\beta_0)$  and infeasible  $JK_I(\beta_0)$  is negligible. Define

$$\Delta_N = \text{Scaled Numerator of } JK(\beta_0) - \underbrace{\text{Scaled Numerator of } JK_I(\beta_0)}_{N_I}$$

$$\Delta_D = \text{Scaled Denominator of } JK(\beta_0) - \underbrace{\text{Scaled Denominator of } JK_I(\beta_0)}_{D_I}$$

To argue that  $|JK(\beta_0) - JK_I(\beta_0)| \rightarrow_p 0$  need to argue

1.  $(\Delta_N, \Delta_D)' \rightarrow_p 0$ ;
2.  $1/D_I$  is bounded in probability.
  - Difficult since  $D_I$  does not have a limiting distribution.
  - Instead directly show that  $\Pr(D_I \leq \delta_n) \rightarrow 0$  for any  $\delta_n \searrow 0$ .

## Lemma 2

Suppose Lemma 1 conditions hold and  $(\Delta_N, \Delta_D)' \rightarrow_p 0$ . Then  $|JK(\beta_0) - JK_I(\beta_0)| \rightarrow_p 0$ .

## Theorem 2

Suppose moment, balanced design, and consistency assumptions  $\boxtimes$  hold. Then, in strengthened local neighborhoods  $\boxtimes$  of  $H_0$ ,

$$\sup_{a \in \mathbb{R}} |\Pr(JK(\beta_0) \leq a) - \Pr(JK_G(\beta_0) \leq a)| \rightarrow 0$$

In particular, under  $H_0$ ,  $JK(\beta_0) \rightsquigarrow \chi^2(1)$ .

# Table of Contents

---

Test Statistic

Power Properties

Empirical Application

General Case

Conditional on  $\tilde{\Pi} := (\tilde{\Pi}_1, \dots, \tilde{\Pi}_n)$ , the gaussian analog  $JK_G(\beta_0) \approx \chi^2(1; \mu_\infty(\tilde{\Pi}))$  where

$$\mu_\infty^2(\tilde{\Pi}) = (\beta - \beta_0)^2 \frac{(\sum_{i=1}^n \Pi_i \tilde{\Pi}_i)^2}{\sum_{i=1}^n \text{Var}(\epsilon_i(\beta_0)) \tilde{\Pi}_i^2}$$

Two main insights:

1. Numerator of  $\tilde{\mu}_\infty^2(\tilde{\Pi})$  suggests that power is maximized when the first stage estimate,  $\tilde{\Pi}_i$ , is close to the true first stage,  $\Pi_i$ .
  - Reflects efficiency bound of [Chamberlain \(1987\)](#).
2. Denominator of  $\tilde{\mu}_\infty^2(\tilde{\Pi})$  suggests having estimates,  $\tilde{\Pi}_i$ , with smaller second moments may increase power.
  - Guides recommendation of ridge regression to construct  $\hat{\Pi}_i$ .

Unfortunately, estimates of  $\Pi_i$  based on  $r = (r_1, \dots, r_n)$  may be biased as mean of  $r_i$  differs from that of  $x_i$  under  $H_1$ ;

$$\mathbb{E}[r_i] = \Pi_i + \rho(z_i)\Pi_i(\beta - \beta_0)$$

Bias is particularly adverse when  $(\beta - \beta_0) = -1/\rho(z_i)$  in which case  $\mathbb{E}[r_i] = 0$ .

- In “low-dimensional” literature, this is dealt with by combining  $K$ -statistic with Anderson-Rubin based on conditioning statistic;
  - [Moreira \(2003\)](#), [Kleibergen \(2005\)](#), [Andrews \(2016\)](#).
- Will take a similar approach, but need to find correct conditioning and mixing statistics.

## Combination Test

---

Combine  $JK(\beta_0)$  test with sup-score test of [Belloni et al. \(2012\)](#). Level  $(1 - \alpha)$  sup-score test rejects if

$$S(\beta_0) := \sup_{\ell \in [d_z]} \left| \frac{\sum_{i=1}^n \epsilon_i(\beta_0) z_{\ell i}}{(\sum_{i=1}^n z_{\ell i}^2)^{1/2}} \right|$$

is larger than the bootstrap critical value;

$$c_{1-\alpha}^S := (1 - \alpha) \text{ quantile of } \sup_{\ell \in [d_z]} \left| \frac{\sum_{i=1}^n e_i \epsilon_i(\beta_0) z_{\ell i}}{(\sum_{i=1}^n z_{\ell i}^2)^{1/2}} \right| \text{ conditional on } \{(y_i, x_i, z_i)\}_{i=1}^n$$

where  $e_1, \dots, e_n$  are i.i.d standard normals generated independently of the data.

Combination test decides whether to run sup-score or jackknife K based on conditioning statistic.

$$C = \sup_{i \in [n]} \left| \frac{\sum_{j \neq i} h_{ij} \hat{r}_j}{\left( \sum_{j \neq i} h_{ij}^2 \right)^{1/2}} \right|.$$

Conditioning statistic attempts to detect whether  $\mathbb{E}[\widehat{\Pi}_i^l] = 0$  for all  $i \in [n]$ ;

# Combination Test

Combination test can be summarized by threshold  $\tau$ ;

$$T(\beta_0; \tau) = \begin{cases} \mathbf{1}\{S(\beta_0) > c_{1-\alpha}^S\} & \text{if } C \leq \tau \\ \mathbf{1}\{JK(\beta_0) > \chi_{1-\alpha}^2(1)\} & \text{otherwise} \end{cases}$$

where  $\chi_{1-\alpha}^2(1)$  is the  $(1 - \alpha)$  quantile of the  $\chi^2(1)$  distribution. In practice, take  $\tau$  to be the 75<sup>th</sup> quantile of conditioning statistic under assumption that  $\mathbb{E}[\widehat{\Pi}_i^I] = 0$  for all  $i \in [n]$ .

## Theorem 3

Suppose the conditions of Theorem 2 hold along with **strengthened moment and balanced design**  conditions. Further, assume  $\log^M(d_z n)/n \rightarrow 0$  for a defined constant  $M$ . Then, the test  $T(\beta_0; \tau)$  has asymptotic size  $\alpha$  for any choice of cutoff  $\tau$ .

Simulating Quantile

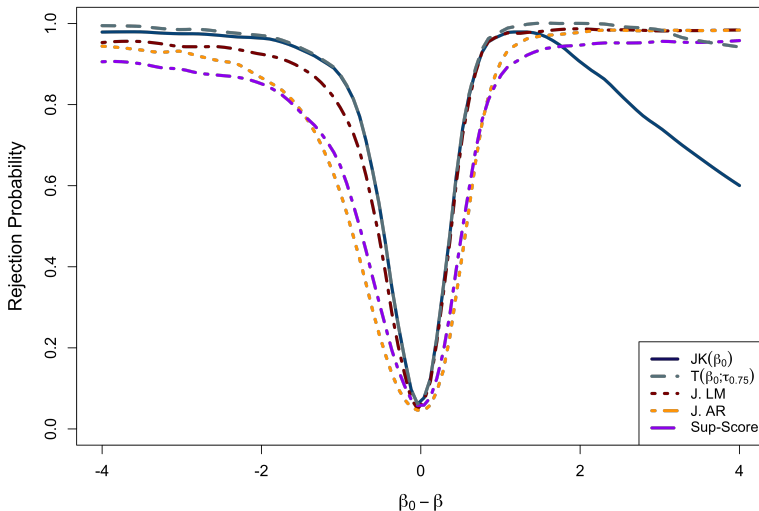

Proof Structure

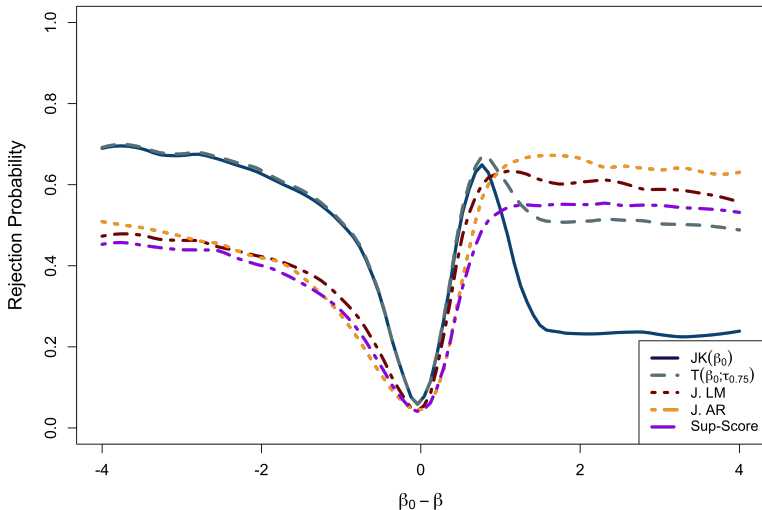

I present simulated power curves following a DGP similar to that of Matsushita and Otsu (2022). Main features:

1. Heteroskedastic laplacian errors  $(\epsilon_i, v_i)$ 
  - Parameter  $\varrho$  controls degree of endogeneity, with  $\varrho = 0$  indicating  $\mathbb{E}[\epsilon_i v_i] = 0$ .
2. Using interactions, quadratic, and cubic powers of 10 initial instruments generate total of 75 instruments.
  - Initial instruments generated multivariate normal with toeplitz covariance structure.
3. Model intermediate identification by dividing first stage signal by  $n^{1/3}$ , for  $n = 500$ .

I compare performance of Jackknife K-test, Combination test, Anderson-Rubin test, and Jackknife LM test.

**Figure 1:** Calibrated Power Curves under intermediate identification strength with  $d_z = 75$ ,  $\rho = 0.3$ , and  $n = 500$

**Figure 2:** Calibrated Power Curves under intermediate identification strength with  $d_z = 75$ ,  $\rho = 0.5$ , and  $n = 500$

# Table of Contents

Test Statistic

Power Properties

Empirical Application

General Case

I apply the proposed testing procedures to the data of [Gilchrist and Sands \(2016\)](#). The data consists of 1671 opening weekend days  $\varnothing$  from 2002 to 2012. For each weekend day,  $i$ , we observe

- The total sales of [wide-released](#)  $\varnothing$  movies  $7w$  days after opening weekend day  $i$ , for  $w = 0, \dots, 5$ .
- A vector of 52 weather related instrumental variables consisting of, for each Saturday and Sunday of the corresponding opening weekend:
  - The proportion of national movie theaters experiencing a maximum temperature in one of sixteen  $5^\circ$  temperature bins from  $[10^\circ, 100^\circ]$ .
  - The proportion of national movie theaters experiencing maximal hourly precipitation in one of six  $0.25''$  precipitation bins from  $[0'', 1.5'']$ .
  - The proportion of national movie theaters experiencing any sort of rainfall.
  - The proportion of national movie theaters experiencing any sort of snowfall.
- A vector of date controls to control for seasonality in movie viewership.

Interested in spillover effects on sales in later weeks from a strong opening weekend.

Formally, interested in parameters  $\beta_w$  for  $w = 1, \dots, 6$  from the linear model

$$\text{Sales}_{wi}^{\perp} = \beta_w \text{Sales}_{0i}^{\perp} + \epsilon_{wi} \quad (3)$$

where

- $\text{Sales}_{0i}^{\perp}$  represents the sales of newly-released movies on opening weekend day  $i$ , after partialling out date controls and a constant.
- For  $w = 1, \dots, 5$ ,  $\text{Sales}_{wi}^{\perp}$  represents the sales of the same movies  $7w$  days after opening day  $i$ , after partialling out date controls and a constant.
- $\text{Sales}_{6i}^{\perp} = \sum_{w=1}^5 \text{Sales}_{wi}^{\perp}$ .

## Initial Instrument Selection

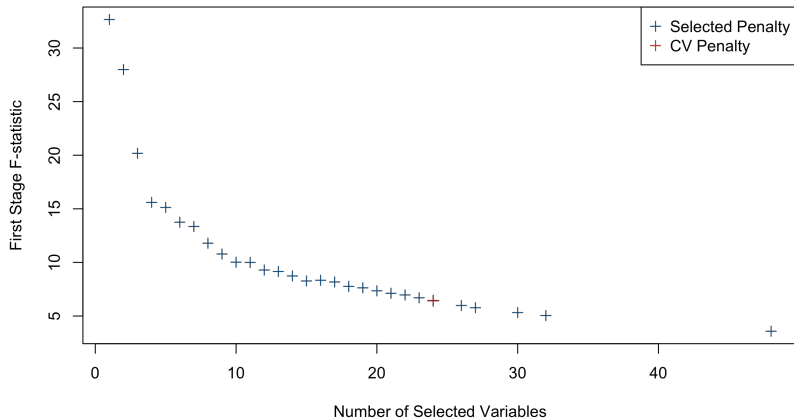

---

In their main analysis, the authors set LASSO penalty to select either one, two, or three instruments. Then run two stage least square on selected instruments.

Instruments Selected	First Stage F-stat.
One Instrument	38.30
Two Instruments	25.86
Three Instruments	20.95
<b>All Instruments</b>	<b>3.804</b>

Identification seems strong when using selected instruments, but weak when using all instruments.

**Gilchrist and Sands F-Statistic by Number of Selected Variables**

Moreover, it is unclear whether F-statistic on selected instruments is interpretable. To demonstrate, I show results from a simple simulated exercise.

- Start with 10 independent weakly relevant instruments
- Generate additional 55 irrelevant instruments by taking all square terms and interactions.
- Set LASSO penalty to select only a certain number of instruments.

Run this simulation 1000 times with  $n = 1000$  and report results from using 2SLS on selected vs. relevant instruments.

## Initial Instrument Selection

---

Compare average F-statistic and 95% Confidence Interval coverage probability from using selected instruments to using oracle estimator which already knows the relevant instruments.

Number of Instruments	<i>Selected Instruments</i>		<i>Oracle Estimator</i>	
	F-stat.	Coverage Prob.	F-stat.	Coverage Prob.
One Instrument	12.539	0.302	4.911	0.904
Two Instruments	11.185	0.150	5.040	0.830
Three Instruments	10.060	0.070	4.820	0.810

Coverage with LASSO selected instruments is much worse despite F-statistics being significantly higher.

## Identification Robust Results

---

Given lack of clarity on identification strength, I revisit the analysis of [Gilchrist and Sands \(2016\)](#) using the identification robust tests proposed above.

## Identification Robust Results

Param.	Estimate	95% Confidence Interval		
		Original	$JK(\beta_0)$	$S(\beta_0)$
$\beta_1$	0.475	[0.428, 0.522]	[0.436, 0.557]	$\emptyset$
$\beta_2$	0.269	[0.223, 0.314]	[0.227, 0.334]	[0.294, 0.334]
$\beta_3$	0.164	[0.131, 0.197]	[0.134, 0.214]	[0.087, 0.094]
$\beta_4$	0.121	[0.096, 0.146]	[0.100, 0.167]	$\emptyset$
$\beta_5$	0.093	[0.073, 0.113]	[0.080, 0.134]	$\emptyset$
$\beta_6$	1.222	[1.077, 1.367]	[1.003, 1.391]	[0.990, 1.518]

Table 2: Confidence Intervals Using 48 Linearly Independent Instruments

In main specification, difference between size of  $S(\beta_0)$  CI and  $JK(\beta_0)$  CI is almost 1.5x difference between length of  $JK(\beta_0)$  CI and original.

## Identification Robust Results

Repeat analysis including interactions between temperature instruments and all other instruments. Resulting confidence intervals are wider than before.

Param.	Estimate	95% Confidence Interval		
		Original	$JK(\beta_0)$	$S(\beta_0)$
$\beta_1$	0.475	[0.428, 0.522]	[0.443, 0.604]	[0.416, 0.477]
$\beta_2$	0.269	[0.223, 0.314]	[0.215, 0.342]	$\emptyset$
$\beta_3$	0.164	[0.131, 0.197]	[0.094, 0.228]	$\emptyset$
$\beta_4$	0.121	[0.096, 0.146]	[0.087, 0.154]	[0.034, 0.121]
$\beta_5$	0.093	[0.073, 0.113]	[0.054, 0.121]	[0.121, 0.208]
$\beta_6$	1.222	[1.077, 1.367]	[0.916, 1.435]	[0.918, 1.562]

Table 3: Confidence Intervals Using 524 Instruments

# Table of Contents

Test Statistic

Power Properties

Empirical Application

General Case

## General Case

---

To this point, have considered a single endogenous variable. Now consider the general case where  $x_i = (x_{1i}, \dots, x_{d_x i})' \in \mathbb{R}^{d_x}$ .

$$\begin{aligned} y_i &= x_i' \beta + \epsilon_i \\ x_{1i} &= \Pi_{1i} + v_{1i} \\ &\vdots \\ x_{d_x i} &= \Pi_{d_x i} + v_{d_x i} \end{aligned} \quad \mathbb{E}[\epsilon_i | z_i] = \mathbb{E}[v_i | z_i] = 0$$

For each  $\ell \in [d_x]$ , construct  $\epsilon_i(\beta_0) := y_i - x_i' \beta_0$  and

$$r_{\ell i} := x_{\ell i} - \epsilon_i(\beta_0) \rho_{\ell}(z_i), \quad \rho_{\ell}(z_i) := \frac{\text{Cov}(\epsilon_i(\beta_0), x_{\ell i} | z_i)}{\text{Var}(\epsilon_i(\beta_0) | z_i)}.$$

Condition analysis on realization of instruments  $\mathbf{z} := (z_1', \dots, z_n')'$ .

For each  $i \in [n]$  and  $\ell \in [d_x]$ , estimate  $\hat{r}_{\ell i}$  and use hat matrix  $H$  to construct

$$\hat{\Pi}_{\ell i} = \sum_{j \neq i} h_{ij} \hat{r}_{\ell j}$$

Collect  $\hat{\Pi}_i = (\hat{\Pi}_{1i}, \dots, \hat{\Pi}_{d_x i}) \in \mathbb{R}^{d_x}$  and define the vectors

$$\epsilon(\beta_0) = (\epsilon_1(\beta_0), \dots, \epsilon_n(\beta_0))' \in \mathbb{R}^n$$

$$\hat{\Pi} = (\hat{\Pi}'_1, \dots, \hat{\Pi}'_n)' \in \mathbb{R}^{n \times d_x}$$

$$\hat{\Pi}_\epsilon = (\epsilon_1(\beta_0)\hat{\Pi}'_1, \dots, \epsilon_n(\beta_0)\hat{\Pi}'_n)' \in \mathbb{R}^{n \times d_x}$$

Test statistic can then be expressed

$$JK(\beta_0) := \epsilon(\beta_0)' \hat{\Pi} (\hat{\Pi}'_\epsilon \hat{\Pi}_\epsilon)^{-1} \hat{\Pi}' \epsilon(\beta_0)$$

Want to apply same argument as before, showing that quantiles of  $JK(\beta_0)$  can be approximated by quantiles of a gaussian analog statistic

$$JK_G(\beta_0) := \tilde{\epsilon}(\beta_0)' \tilde{\Pi} (\tilde{\Pi}'_e \tilde{\Pi}_e)^{-1} \tilde{\Pi}' \tilde{\epsilon}(\beta_0)$$

where  $\tilde{\Pi}$ ,  $\tilde{\Pi}_e$ , and  $\tilde{\epsilon}(\beta_0)$  are constructed using  $(\tilde{\epsilon}_i(\beta_0), \tilde{r}_{1i}, \dots, \tilde{r}_{d_x i})'$  generated

- Independently of data and across indices
- According to a gaussian distribution with the same mean and covariance matrix as  $(\epsilon_i(\beta_0), r_{1i}, \dots, r_{d_x i})'$

Under  $H_0$ ,  $JK_G(\beta_0) \sim \chi^2(d_x)$ .

Showing approximation when  $d_x > 1$  requires a modification of original argument

- When  $d_x = 1$ , relied on observation that

$$JK(\beta_0) = \frac{N}{D} \leq a \iff JK^a = N - aD \leq 0$$

In general, have to work directly with form of test statistic.

Showing approximation when  $d_x > 1$  requires a modification of original argument

- When  $d_x = 1$ , relied on observation that

$$JK(\beta_0) = \frac{N}{D} \leq a \iff JK^a = N - aD \leq 0$$

In general, have to work directly with form of test statistic.

- When  $\lambda_{\min}(\widehat{\Pi}'_{\epsilon}\widehat{\Pi}_{\epsilon}) \approx 0$ , derivatives of  $JK(\beta_0)$  may become arbitrarily large. This poses a problem for interpolation argument.

Showing approximation when  $d_x > 1$  requires a modification of original argument

- When  $d_x = 1$ , relied on observation that

$$JK(\beta_0) = \frac{N}{D} \leq a \iff JK^a = N - aD \leq 0$$

In general, have to work directly with form of test statistic.

- When  $\lambda_{\min}(\widehat{\Pi}'_\epsilon \widehat{\Pi}_\epsilon) \approx 0$ , derivatives of  $JK(\beta_0)$  may become arbitrarily large. This poses a problem for interpolation argument.
- To get around this, use a data-dependent choice of functions  $\varphi(\cdot)$  to approximate  $\mathbf{1}\{\cdot \leq a\}$ 
  - Data dependent  $\varphi(\cdot)$  has small derivatives in directions where  $\lambda_{\min}(\widehat{\Pi}'_\epsilon \widehat{\Pi}_\epsilon) \approx 0$ .

Showing approximation when  $d_x > 1$  requires a modification of original argument

- When  $d_x = 1$ , relied on observation that

$$JK(\beta_0) = \frac{N}{D} \leq a \iff JK^a = N - aD \leq 0$$

In general, have to work directly with form of test statistic.

- When  $\lambda_{\min}(\widehat{\Pi}'_{\epsilon}\widehat{\Pi}_{\epsilon}) \approx 0$ , derivatives of  $JK(\beta_0)$  may become arbitrarily large. This poses a problem for interpolation argument.
- To get around this, use a data-dependent choice of functions  $\varphi(\cdot)$  to approximate  $\mathbf{1}\{\cdot \leq a\}$
- Establish anticoncentration bound;  $\Pr(\lambda_{\min}(\tilde{\Pi}'_{\epsilon}\tilde{\Pi}_{\epsilon}) \leq \delta_n) \rightarrow 0$  whenever  $\delta_n \searrow 0$ .
  - Allows quality of approximation to improve with sample size.

Modified interpolation argument relies on stronger moment conditions.

### Theorem 4

Suppose that strengthened moment conditions  $\boxtimes$  hold along with generalizations of the balanced design and consistent estimation conditions  $\boxtimes$ . Then in local neighborhoods  $\boxtimes$  of the null:

$$\sup_{a \in \mathbb{R}} \left| \Pr(JK(\beta_0) \leq a) - \Pr(JK_G(\beta_0) \leq a) \right| \rightarrow 0$$

In particular, under  $H_0$ ,  $JK(\beta_0) \rightsquigarrow \chi^2(d_x)$ .

Also propose a combination test based on the generalized conditioning statistic

$$C := \min_{1 \leq \ell \leq d_x} \max_{1 \leq i \leq n} \left| \frac{\sum_{j \neq i} h_{ij} \hat{r}_j}{\left( \sum_{j \neq i} h_{ij}^2 \right)^{1/2}} \right|$$

After looking at value of  $C$ , researcher can decide whether to use sup-score test or test based on  $JK(\beta_0)$ ;

$$T(\beta_0; \tau) = \begin{cases} \mathbf{1}\{S(\beta_0) > c_{1-\alpha}^S\} & \text{if } C \leq \tau \\ \mathbf{1}\{JK(\beta_0) > \chi_{1-\alpha}^2(d_x)\} & \text{otherwise} \end{cases}$$

### Theorem 4

Suppose that strengthened moment conditions  $\checkmark$  hold along with generalizations of the balanced design and consistent estimation conditions  $\checkmark$ . Then the combination test has asymptotic size  $\alpha$  for any choice of cutoff  $\tau$ .

This paper proposes a new test for the structural parameter in a linear IV model. This proposed test

1. Has exact asymptotic size so long as a nuisance parameter can be consistently estimated. This is possible under approximate sparsity even when  $d_z \gg n$  but does not require  $d_z \rightarrow \infty$ .
2. Can be combined with the sup-score test to improve power against certain alternatives.
3. Is shown to perform well in an empirical application and simulation study.

This paper proposes a new test for the structural parameter in a linear IV model. This proposed test

1. Has exact asymptotic size so long as a nuisance parameter can be consistently estimated. This is possible under approximate sparsity even when  $d_z \gg n$  but does not require  $d_z \rightarrow \infty$ .
2. Can be combined with the sup-score test to improve power against certain alternatives.
3. Is shown to perform well in an empirical application and simulation study.

Thank you all very much

## Ridge Penalty

---

Following recommendations in [Harrell \(2015\)](#), [Wieringen \(2023\)](#), set ridge penalty parameter so effective degrees of freedom is no more than a fraction of sample size:

$$\lambda^* := \inf\{\lambda \geq 0 : \text{trace}(\mathbf{z}(\mathbf{z}'\mathbf{z} + \lambda I_{d_z})^{-1}\mathbf{z}') \leq n/5\}$$

## Alternate Hat Matrices

---

Alternate choices of hat matrix could include

1. A “true” jackknife OLS / Ridge,

$$\widehat{\Pi}_i = \mathbf{z}'_i \widehat{\phi}_{(-i)}$$

where  $\widehat{\phi}_{(-i)}$  is the OLS / Ridge regression parameter from regressing  $r_{(-i)}$  on  $\mathbf{z}_{(-i)}$

2. The deleted diagonal projection matrix of [Chao et al. \(2012\)](#) used in [Crudu et al. \(2021\)](#), [Mikusheva and Sun \(2021\)](#), [Matsushita and Otsu \(2022\)](#);

$$[H]_{ij} = [\mathbf{z}(\mathbf{z}'\mathbf{z})^{-1}\mathbf{z}]_{ij}\mathbf{1}\{i \neq j\}$$

3. Any hat matrix resulting from a preliminary unsupervised learning to reduce the dimensionality of  $\mathbf{z}$ , such as PCA.

## Verifying Balanced Design

---

A sufficient condition for the balanced design requirement is that there is a fixed quantile  $q \in (0, 100)$  such that

$$\frac{q^{\text{th}} \text{ quantile of } \mathbb{E}[(\sum_{j \neq i} h_{ij} r_j)^2]}{\max_i \mathbb{E}[(\sum_{j \neq i} h_{ij} r_j)^2]} \text{ is bounded away from zero}$$

## Definitions

---

1. **Approximate Sparsity** Function  $\rho(z_i)$  has an approximate sparse representation in basis  $b(z_i) \in \mathbb{R}^{d_b}$ ; there exists a  $\gamma \in \mathbb{R}^{d_b}$  such that  $\rho(z_i) = b(z_i)' \gamma + \xi_i$  and

(a)  $s = \{j : \gamma_j \neq 0\}$  satisfies  $s^2 \log^M(d_b n) n \rightarrow 0$

(b)  $(\frac{1}{n} \sum_{i=1}^n \xi_i^2)^{1/2} = o(n^{-1/2})$

 Back

2. **Balanced Design** Let  $\widehat{\Pi}_i^I := \sum_{j \neq i} h_{ij} r_j$ . Assume that there is a constant  $c > 1$  such that

$$\frac{\max_i \mathbb{E}[(\widehat{\Pi}_i^I)^2]}{\frac{1}{n} \sum_{i=1}^n \mathbb{E}[(\widehat{\Pi}_i^I)^2]} \leq c$$

Plus a technical condition requiring that the hat matrix  $H$  is contracted using  $> 1$  effective instrument.

 Back

# Limiting Distribution Assumptions

---

For any  $\nu > 0$  and random variable  $X$ , define the Orlicz quasi-norm

$$\|X\|_{\psi_\nu} = \inf\{t > 0 : \mathbb{E} \exp(|X|^\nu / t^\nu) \leq 2\}$$

1. **Moment Assumptions** There is a constant  $c > 1$  and  $\nu \in (0, 1] \cup \{2\}$  such that  $\|\epsilon_i\|_{\psi_\nu} \leq c$  and  $c^{-1} \leq \mathbb{E}[|\epsilon_i|^l |r_i|^k] \leq c$  for any  $i \in [n]$  and  $0 \leq l + k \leq 6$ .
2. **Balanced Design** Let  $\widehat{\Pi}_i^l := \sum_{j \neq i} h_{ij} r_j$ . Assume that there is a constant  $c > 1$  such that

$$\frac{\max_i \mathbb{E}[(\widehat{\Pi}_i^l)^2]}{\frac{1}{n} \sum_{i=1}^n \mathbb{E}[(\widehat{\Pi}_i^l)^2]} \leq c$$

Plus a technical condition requiring that the hat matrix  $H$  is constructed using  $> 1$  effective instrument.

3. **Consistency** The function  $\rho(z_i)$  has an approximately sparse representation in basis  $b(z_i)$  and researcher has access to an estimator  $\widehat{\gamma}$  that satisfies  $\|\widehat{\gamma} - \gamma\|_1 \rightarrow_p 0$ .

## Infeasible Local Power Assumptions

---

For any  $\nu > 0$  and random variable  $X$ , define the Orlicz quasi-norm

$$\|X\|_{\psi_\nu} = \inf\{t > 0 : \mathbb{E} \exp(|X|^\nu / t^\nu) \leq 2\}$$

1. **Moment Assumptions** There is a constant  $c > 1$  such that  $\mathbb{E}[|\epsilon_i|^l |r_i|^k] \leq c$  for any  $i \in [n]$  and  $0 \leq l + k \leq 6$ .
2. **Balanced Design** Let  $\widehat{\Pi}_i^l := \sum_{j \neq i} h_{ij} r_j$ . Assume that there is a constant  $c > 1$  such that

$$\frac{\max_i \mathbb{E}[(\widehat{\Pi}_i^l)^2]}{\frac{1}{n} \sum_{i=1}^n \mathbb{E}[(\widehat{\Pi}_i^l)^2]} \leq c$$

Plus a technical condition requiring that the hat matrix  $H$  is constructed using  $> 1$  effective instrument.

## Local Neighborhoods and Consistency

---

Define  $s_n := \max_i \mathbb{E}[(\widehat{\Pi}_i^I)^2]$  and the local power index  $P$

$$P := \mathbb{E} \left[ \left( \frac{s_n}{\sqrt{n}} \sum_{i=1}^n \Pi_i \widehat{\Pi}_i^I \right)^2 \right]$$

Local neighborhoods are characterized by (i)  $P$  being bounded and (ii) a technical condition roughly requiring that  $|\mathbb{E}[\epsilon_i(\beta_0)]| \lesssim |\mathbb{E}[r_i]|$ .

### Proposition 1

If the second condition is satisfied and  $P \rightarrow \infty$ , then the test based on  $JK_I(\beta_0)$  is consistent.

## Consistency Sketch

---

The consistency result relies on showing that  $\Pr(N_I^2 - aD_I \leq 0) \rightarrow 0$  for any  $a \in \mathbb{R}_+$ , where  $N_I$  is the scaled numerator of  $JK_I(\beta_0)$  and  $D_I$  is the scaled denominator of  $JK_I(\beta_0)$ .

1. Scaled denominator is bounded in probability, suffices to show that  $\Pr(|N_I| \leq M) \rightarrow 0$  for any fixed  $M$ .
2. Statement  $\Pr(|N_I| \leq M) \rightarrow 0$  for any fixed  $M$  follows if  $\text{Var}(N_I) = O(1)$  and  $\mathbb{E}[N_I^2] \rightarrow \infty$ , since  $\text{Var}(|N_I|) = \mathbb{E}[N_I^2] - (\mathbb{E}[|N_I|])^2 \leq \text{Var}(N_I)$ .
3. The power index  $P$  represents the second moment of the scaled numerator,  $N_I$ . Under additional regularity condition, can show that  $\text{Var}(N_I) = O(1)$ .

## Local Neighborhoods

---

Local Neighborhoods are defined by

1. The local power index  $P$  is bounded,  $P \leq c$ .

$$P := \mathbb{E} \left[ \left( \frac{s_n}{\sqrt{n}} \sum_{i=1}^n \Pi_i \widehat{\Pi}_i^l \right)^2 \right]$$

2. A technical condition roughly requiring that  $|\mathbb{E}[\epsilon_i(\beta_0)]| \lesssim |\mathbb{E}[r_i]|$  for all  $i \in [n]$ .

## Strengthened Local Neighborhoods

---

Local Neighborhoods are defined by

1. The local power index  $P$  is bounded,  $P \leq c$ .

$$P := \mathbb{E} \left[ \left( \frac{s_n}{\sqrt{n}} \sum_{i=1}^n \Pi_i \widehat{\Pi}_i^l \right)^2 \right]$$

2. A technical condition roughly requiring that  $|\mathbb{E}[b_\ell(z_i)\epsilon_i(\beta_0)]| \lesssim |\mathbb{E}[r_i]|$  for all  $i \in [n]$  and  $\ell \in [d_b]$ .

## Combination Test

---

In practice, I take  $\tau$  to be the 40<sup>th</sup> quantile of conditioning statistic under assumption that  $\mathbb{E}[\widehat{\Pi}_i^I] = 0$  for all  $i \in [n]$ . Simulated;

$$\tau = 40^{\text{th}} \text{ quantile of } \sup_{i \in [n]} \left| \frac{\sum_{j \neq i} e_j h_{ij} \hat{r}_j}{\left( \sum_{j \neq i} h_{ij}^2 \right)^{1/2}} \right| \text{ conditional on } \{y_i, x_i, z_i\}_{i=1}^n$$

where  $e_1, \dots, e_n$  are i.i.d standard normal generated independently of the data.

## Combination Test Conditions

---

In addition to the conditions of Theorem 2, assume that there is a constant  $c > 1$  such that

1. There is a  $\nu \in (0, 1] \cup \{2\}$  such that  $\|r_i\|_{\psi_\nu} \leq c$ ;
2. The instruments and hat matrix are balanced in the sense that

$$\max_{\ell,i} \left| \frac{z_{\ell i}}{\left(\frac{1}{n} \sum_{i=1}^n z_{\ell i}^2\right)^{1/2}} \right| + \max_{i,j} \left| \frac{h_{ij}}{\left(\frac{1}{n} \sum_{i=1}^n h_{ij}^2\right)^{1/2}} \right| \leq c$$

3.  $\log^{7+4/\nu}(d_z n) \rightarrow 0$ .

## Empirical Details

---

- **Wide Released** Displayed in over 600 theaters nationally during its run.
- **Opening Weekend Day** A Friday, Saturday, or Sunday of opening weekend.

 Back

## Modified Interpolation Conditions

---

Recall that for any  $\nu > 0$  the Orlicz-norm is defined

$$\|X\|_{\psi_\nu} = \min t > 0 : \mathbb{E} \exp(|X|^\nu / t^\nu) \leq 2$$

1. **Moment Conditions** There is a  $c > 1$  and  $\nu \in (0, 1] \cup \{2\}$  such that  $\|\epsilon_i(\beta_0)\|_\nu \leq c$  and  $\|r_i\|_\nu \leq c$  and  $c^{-1} \leq$  for all  $i \in [n]$ .
2. **Balanced Design** The general balanced design condition requires that for any  $\alpha \in \mathbb{R}^{d_x}$

$$c^{-1} \leq \frac{\mathbb{E}[\frac{1}{n} \sum_{i=1}^n (\sum_{\ell=1}^{d_x} \alpha_\ell \widehat{\Pi}_{\ell i}^I)^2]}{(\sum_{\ell=1}^{d_x} \alpha_\ell \max_i \mathbb{E}[(\widehat{\Pi}_{\ell i}^I)^2])^2}$$

as well as a condition requiring that the hat matrix is constructed using more than one “effective” instrument.

3. **Consistency** Each function  $\rho_\ell(z_i)$  has an approximately sparse representation in the basis  $b(z_i)$ ,  $\rho_\ell(z_i) = b(z_i)' \gamma_\ell + \xi_{\ell i}$ , and the researcher has access to an estimators  $\widehat{\gamma}_\ell$ ,  $\ell \in [d_x]$ , that satisfy  $\|\widehat{\gamma}_\ell - \gamma_\ell\|_1 \rightarrow_p 0$ .

## Generalized Local Neighborhood

---

The multivariate local power index is given

$$P = \sum_{\ell=1}^{d_x} \mathbb{E} \left[ \left( \frac{s_{\ell,n}}{\sqrt{n}} \sum_{i=1}^n \hat{\Pi}_{\ell,i}^I \Pi_i' (\beta - \beta_0) \right)^2 \right]$$

And generalized local neighborhoods are defined by

- (a)  $P$  is bounded,
- (b) A technical condition roughly requiring both  $|\mathbb{E}[\epsilon_i(\beta_0)]| \lesssim \mathbb{E}[r_i]$  and  $|\mathbb{E}[b(z_i)\epsilon_i(\beta_0)]| \lesssim \mathbb{E}[r_i]$ .

## Combination Test

---

Proof of Theorem 3 follows the basic structure;

1. Establish that quantiles of  $(JK(\beta_0), S(\beta_0), C)$  can be jointly uniformly approximated by quantiles of gaussian analogs  $(JK_G(\beta_0), S_G(\beta_0), C_G)$ .

## Combination Test

---

Proof of Theorem 3 follows the basic structure;

1. Establish that quantiles of  $(JK(\beta_0), S(\beta_0), C)$  can be jointly uniformly approximated by quantiles of gaussian analogs  $(JK_G(\beta_0), S_G(\beta_0), C_G)$ .
2. Under  $H_0$ ,  $JK_G(\beta_0) \perp C_G$  and  $S_G(\beta_0) \perp C_G$ .

## Combination Test

---

Proof of Theorem 3 follows the basic structure;

1. Establish that quantiles of  $(JK(\beta_0), S(\beta_0), C)$  can be jointly uniformly approximated by quantiles of gaussian analogs  $(JK_G(\beta_0), S_G(\beta_0), C_G)$ .
2. Under  $H_0$ ,  $JK_G(\beta_0) \perp C_G$  and  $S_G(\beta_0) \perp C_G$ .
3. Using independence, does not matter if we look at  $C$  before deciding to run  $JK(\beta_0)$  or  $S(\beta_0)$  test.
  - Only use marginal independence for thresholding test. More sophisticated combinations would require joint independence;  $(JK_G(\beta_0), S_G) \perp C_G$ .
